ABSTRACT

The number of vulnerabilities that are vulnerable to being hacked and exploited by people who are not responsible for stealing data and information can be caused because the parties attacked do not realize how important network security is to be applied to the system they have.

Honeypot is a network security that aims to build a server that resembles the original server and serves to trap the attacker.

In this final project, Honeypot was built using Honeytrap. Honeytrap is used to secure the Web Server from attacks on SSH *(Secure Shell)*

Keywords: *Honeypot, Honeytrap, Secure Shell, Web Server.*
